Note

- Instructions have been included for each segment. You do not have to follow them exactly, but they are included to help you think through the steps.

Analysis

First Observation

Cloudiness and Wind Speed do not appear to follow particular trends around the Equator in comparison to the rest of the world. This is a reasonable result because clouds are pushed by wind and wind is not necessarily linked to geographical location (in my understanding).

Second Observation

Humidity appears to be slightly higher at the Equator than at other latitudes, however this is a small observation. It may be more conclusive to compare dew point in addition to humidity to draw more conclusions.

Third Observation

Temperature does appear to follow a trend: the average temperature reaches a peak between -20 and +20 latitude. Therefore, we can conclusively say that the temperature is high at and near the Equator.

```
# pip install citipy
```

Generate Cities List

In [23]:

```
# List for holding lat_lngs and cities
lat_lngs = []
cities = []

# Create a set of random lat and lng combinations
lats = np.random.uniform(low=-90.000, high=90.000, size=1500)

lat_lngs = zip(lats, lngs)

# Identify nearest city for each lat, lng combination, must be a list of unique cities
for lat_lng in lat_lngs:
    city = citipy.nearest_city(lat_lng[0], lat_lng[1]).city_name

    if city not in cities:
        cities.append(city)

# Print the city count

Perform API Calls

- Perform a weather check on each city using a series of successive API calls.
- Include a print log of each city as it's being processed (with the city number and city name).
